ABSTRACT

Cultural practices may either enhance or interfere with evolved preferences as predicted by culture–gene coevolution theory. Here, we investigated the impact of artificial fragrances on the assessment of biologically relevant information in human body odor. To do this, we examined cross-sensory consistency (across faces and odors) in the perception of masculinity and femininity in men and women, and how consistency is influenced by the use of artificial fragrance. Independent sets of same and opposite-sex participants rated odor samples (with and without a fragrance, $n = 239$ raters), and photographs ($n = 130$) of 20 men and 20 women. In female, but not male raters, judgments of masculinity/femininity of non-fragranced odor and faces were correlated. However, the correlation between female ratings of male facial and odor masculinity was not evident when assessing a fragranced body odor. Further analysis also indicated that differences in ratings of male odor masculinity between men with high and low levels of facial masculinity were not present in fragranced body odor samples. This effect was absent in ratings of female odors by both female and male raters, suggesting sex-specificity in the effects of fragrance on odor perception. Our findings suggest that women may be more attentive to these odor cues, and therefore also to disruption of this information through fragrance use. Our results show that cultural practices might both enhance and interfere with evolved preferences.

1. Introduction

It is well-established that many non-human species use olfactory information to assess potential mates on attributes such as reproductive status (Clarke, Barrett, & Henzi, 2009; Miranda, Almeida, Hubbard, Barata, & Canário, 2005), competitive ability (Huck, Banks, & Wang, 1981; Rich & Hurst, 1998) and genetic compatibility (Ilmonen, Stundner, Thoss, & Penn, 2009; Ruther, Matschke, Garbe, & Steiner, 2009). Additionally, olfactory cues not only reveal characteristics of the individual, but have also been found to induce physiological and behavioral changes in the perceiver, such as accelerating or delaying the onset of puberty, inducing ovulation/abortion, increasing and decreasing sperm allocation as well as affecting the performance of copulatory behaviors in many non-human animals (for a review see Petruelis, 2013). Humans, however, have a reduced number of olfactory receptor cells and functional olfactory receptor genes compared to other mammals, such as dogs and mice (Schaal & Porter, 1991; Young, 2002). This has

previously led to the conclusion that humans are chiefly visual creatures. However, while we may be inferior to other species in regards to our ability to detect odors, we are in fact quite well endowed with sebaceous and apocrine glands (Kippenberger et al., 2012); this led Stoddart (1990) to label humans as 'the scented ape'. The apocrine glands become active during puberty (Montagna & Parakkal, 1974), suggesting a potential role in sexual selection. Based on such information, it has been hypothesized that humans retain the ability to assess olfactory cues in mate choice scenarios, with body odor posited as serving an analogous signaling function in humans to urinary and glandular odor cues in other animals (Comfort, 1971; Penn et al., 2007; Schleidt, Hold, & Attili, 1981; Stoddart, 1990).

In support of this, research suggests that humans indeed use olfactory cues present in odor to assess a range of qualities. For example, humans can assess an individual's sex (Schleidt et al., 1981), personality (Sorokowska, 2013), diet (Fialová, Roberts, & Havlíček, 2013), genetic compatibility (Havlicek & Roberts, 2009; Havlíček & Roberts, 2013) and health status (Moshkin et al., 2012) via odor. Humans also have the capacity to recognize kin via body odor (Ferdenzi, Schaal, & Roberts, 2010; Roberts et al., 2005; Weisfeld, Czilli, Phillips, Gall, & Lichtman, 2003), which is important in sexual selection in order to avoid inbreeding. Individuals can assess olfactory cues of a woman's menstrual cycle stage, with studies finding that men perceive female odors collected

during the follicular phase of the menstrual cycle to be more attractive than those from the luteal phase, the latter being associated with a low conception risk (Singh & Bronstad, 2001; Gildersleeve, Haselton, Larson, & Pillsworth, 2012; Kuukasjärvi et al., 2004). Furthermore, findings to date demonstrate that information which is available in body odor is often correlated with mate-choice relevant information present in cues from other modalities. For example, individuals prefer the smell of others who exhibit attractive nonverbal behavior (Roberts et al., 2011) or low fluctuating asymmetry, believed to reflect genetic and developmental stability, who are also often rated as being more attractive facially (Rikowski & Grammer, 1999; Thornhill & Gangestad, 1999). Additionally, previous studies suggest that these olfactory cues may not only provide information, but, as found with non-human animals, potentially alter the physiological state of the perceiver. For example, Bensafi et al. (2003) found that presentation of a human sex steroid derived compound lead to increased physiological arousal in women and decreased arousal in men.

In spite of the apparent value of olfactory cues in evaluating others, there are a number of cultures where conscious detection of body odor is perceived negatively (e.g., Schleidt et al., 1981). This is echoed in the early development and use of fragrances and perfumes worldwide, which dates back to at least the ancient Egyptian and Greek civilizations (Stoddart, 1990). Indeed, the fragrance industry in western societies is worth billions of dollars, and personal fragrance use is widespread, with one study finding that 79% of women and 60% of men sampled in the UK reported using a deodorant every day (Roberts, Miner, & Shackelford, 2010). The use of such products raises the question of what effect they might have on the cues present in body odor, and in turn how this influences social and sexual interactions with others. Indeed, it was reported that videos of men who used fragranced antiperspirants were judged as more attractive compared to videos of men who used the placebo; perhaps due to changes in self-confidence of the target men (Roberts et al., 2009).

One model that has been employed to help explain the apparent contradiction between the communicatory significance of body odor and our apparent desire to repress it is the culture–gene coevolution paradigm. According to this paradigm, the cultural attitudes, beliefs, practices and perceptions of others can be selected in a similar fashion to that of genetic material and as such these cultural norms and behaviors are subject to a process analogous to natural selection (Feldman & Laland, 1996; Richerson & Boyd, 2006). Consequently, it has been posited that this contradiction regarding olfaction and fragrance may represent an interaction between culturally evolved practices and biologically evolved olfactory signals. Indeed it has been proposed that biologically evolved preferences might even shape cultural practices. Havlíček and Roberts (2013) discuss the use of cosmetics in this regard, an example of this being that individuals may wear foundation in order to improve the appearance of skin health—a biologically evolved preference being enhanced via a cultural practice. In support of this, one study found there to be greater contrast in the luminance of females' faces than males', and that gender assumptions of androgynous faces could be manipulated by increasing or decreasing the luminosity contrast of images (Russell, 2009). Furthermore, the author found that the same face had higher levels of contrast when makeup was applied compared to having no makeup applied, lending support to the concept that facial cosmetics are used to enhance sexually dimorphic attributes, in this case femininity, which may play a role in human mate choice.

Based on this framework, recent research suggests that rather than completely masking cues present in body odor, fragrances may instead be chosen (perhaps unintentionally) to enhance the unique qualities of an individual's body odor. For instance, it has been shown that preferences for common perfume ingredients relate to the major histocompatibility complex (MHC), a set of genes involved in immune function (Hämmerli, Schweisgut, & Kaegi, 2012; Milinski & Wedekind, 2001). MHC is potentially an important cue of genetic compatibility in humans,

as in other species, and MHC-disassortative odor preferences have been recorded (Havlíček & Roberts, 2013). MHC-correlated perfume choice may thus enhance idiosyncratic immunogenetic cues available in body odor and used in mate choice, as predicted by the culture–gene coevolution paradigm. In further support of this, Lenochová et al. (2012) found that mixtures of participants' body odor with their perfume of choice were perceived to be more pleasant than mixtures of body odor and an experimenter-assigned perfume, suggesting choice for fragrances that complement underlying body odor. However, how fragrance use may interfere with odor-based discrimination of other mate qualities has not yet been explored.

In order to clarify this issue, we investigated the effects of fragrance use on perceptions of masculinity and femininity in men and women. These traits have been previously linked to mate choice and sexual selection in humans, with masculinity potentially reflecting underlying genetic quality in males (Thornhill & Gangestad, 1999) and femininity being identified as a trait representing reproductive potential in human females (e.g. Fraccaro et al., 2010). Both traits are detectable across multiple modalities (Fraccaro et al., 2010; Little, Connely, Feinberg, Jones, & Roberts, 2011), with perceptions of facial masculinity having recently been found to correlate with sexually dimorphic traits such as height and weight (Holzleitner et al., 2014). Additionally, both traits are central constructs used in the commercial development of fragrances, with most perfumes and deodorants being classified as either masculine or feminine (so-called unisex fragrances are in the minority; Lindqvist, 2012). This further cements the cultural relevance of these sexually dimorphic traits for males and females, making them prime candidates for cultural practices which may have emerged as a result of biologically evolved preferences. Fragrances, as with other cosmetics, may be designed and used to enhance the perception of these traits, thus making an individual more appealing to the opposite sex.

The current study aimed to investigate whether commercially available fragranced products lead to changes in ratings of masculinity/femininity. This would be predicted by a culture–gene coevolution framework where cultural norms might be shaped by evolved, sexually dimorphic, preferences. Alternatively, the cultural practices might interfere with the evolved preferences. If this would be the case, fragranced products would decrease discrimination of masculinity/femininity. In order to assess these hypotheses, we first aimed to replicate previous findings that these mate-choice relevant, sexually dimorphic traits assessed using one modality are correlated with the assessments of the same trait in another modality. This was accomplished by examining the relationship between odor rated and facially rated masculinity/femininity. By comparison of these cross-modal relationships between faces and axillary odor, with and without the presence of a fragrance, we were able to investigate the impact that fragrance had on the assessment of individuals' odor, here taken as representing one aspect of their attractiveness to a potential mate. We hypothesized that fragranced odor samples would be rated as more masculine or feminine than unfragranced samples (in keeping with a culture–gene coevolution paradigm). Furthermore, we predicted that the ratings of masculinity and femininity given to male and female *unfragranced* axillary odors would be correlated with the ratings given to the same individuals' faces. Finally, we hypothesized that the presence of an artificial fragrance would lead to biased assessment of an individual's masculinity/femininity through body odor, thus resulting in no correlation between fragranced odor ratings and face ratings of masculinity/femininity, as fragrances are specifically designed to enhance these traits reducing the individual variation in these underlying body odor cues (Lindqvist, 2012).

2. Method

The study received ethical approval from the University of Stirling's Psychology Ethics Committee.

2.1. Odor donors

Odor samples were collected from 20 men (mean age \pm SD = 23.25 \pm 4.23; range: 19–33) and 20 women (21.2 \pm 2.50; range: 18–27) recruited from the University of Stirling, all of whom were heterosexual non-smokers who regularly wore deodorant. We restricted our recruitment of female odor donors to women who were using hormonal contraception, in order to control for cyclical hormonal changes which are known to influence women's body odor (Gildersleeve et al., 2012; Havlíček, Dvorakova, Bartos, & Flegr, 2006).

We collected two axillary odor samples from each donor: one while donors were wearing no underarm fragrance (hereafter termed the 'unfragranced sample') and one while donors were wearing their usual underarm fragrance (hereafter termed 'fragranced sample'). The two odor collection periods were on consecutive days (unfragranced followed by fragranced), and donors were instructed to shower in between the two periods. Odor was collected on cotton pads which participants attached to their armpits, using surgical tape, and left in place for 24 hours. There is variation in sampling time across studies, though numerous studies to date have adopted 24 hour sampling periods for odor collection (e.g. Kohoutová, Rubešová, & Havlíček, 2011; Martins et al., 2005; Santos, Schinemann, Gabardo, & Bicalho, 2005; Sorokowska, Butovskaya, & Veselovskaya, 2015). Furthermore Havlíček, Lenochová, Oberzaucher, Grammer, and Roberts (2011) found that 12 hour sampling yielded samples which were less intense, and less likely to be perceived, compared with a 24 hour sampling period. Each donor was provided with fragrance free soap (Simple Pure™) and asked to use only this in place of any fragranced hygiene products for 24 hours prior to odor collection, and in between the two odor collection periods. For the fragrance free sample participants simply showered, dried, and then applied the cotton pads to their armpits. For the fragranced samples participants showered and then once dry applied their usual deodorant to each armpit before applying the cotton pads provided. They were also asked to avoid wearing any other fragranced products or perfumes. In line with previous research, we instructed our donors to avoid drinking alcohol, being in smoky places, exercising and eating certain strong-smelling foods (e.g., garlic, asparagus, and curry). They were asked to refrain from sexual activity and to avoid sharing their bed with anyone during the odor collection phase (Kohoutová et al., 2011; Lenochová et al., 2012; Roberts et al., 2011). The donors returned the samples, in sealed plastic bags, to the lab within 2 hours of removal, where they were stored in a freezer at -30 °C until use. Samples were thawed at room temperature for 2 hours prior to test sessions and re-frozen between test sessions. Previous research suggests freezing has minimal impact on the perceptual quality of odor samples (Lenochová, Roberts, & Havlíček, 2009; Roberts, Gosling, Carter, & Petrie, 2008).

Finally, digital color facial photographs were taken of each donor (head and shoulders) in standardized lighting conditions, at a standard 1.5 m distance against a neutral gray background, using a Canon PowerShot G6 digital camera (7.1 megapixel, focal length range of 7.2 to 28.8 mm). For the purpose of the photo, participants were instructed to adopt a neutral expression. All participants were requested to remove make-up beforehand, and to remove glasses, jewelry and facial piercings.

2.2. Odor raters

Odor samples were rated by 275 same and opposite-sex raters. We excluded scores if raters did not complete all of the ratings ($n = 23$), indicated they were homosexual ($n = 12$) or answered 'prefer not to say' with regard to their sexual orientation ($n = 1$), leaving a total of 239 raters used in analyses.

Male odor samples were rated by a total of 75 women (mean age \pm SD = 20.12 \pm 2.39; range: 17–30), and by 45 men (21.26 \pm 4.16; range: 18–40). Female odor samples were rated by an independent set of 75

women (21.67 \pm 4.05; range: 18–49) and 44 men (21.25 \pm 2.01; range: 19–26).

2.3. Face raters

Participants were an independent set of 204 individuals recruited via online social networking sites, and were not familiar with the individuals they were rating. As with odor ratings, incomplete responses ($n = 65$) and those from raters who were homosexual ($n = 6$) or who chose 'prefer not to say' ($n = 3$) when completing the sexual orientation question were excluded, leaving a total of 130 raters used in the analysis. For the male face rating task, the final sample of raters included 42 women (mean age \pm SD = 28.26 \pm 9.61; range: 21–62) and 16 men (30.81 \pm 11.37; range: 23–62). Female faces were rated by an independent set of 54 women (24.99 \pm 8.28; range: 18–54) and 18 men (30.17 \pm 10.39; range: 19–49).

2.4. Odor rating procedure

After providing informed consent, participants were asked for some basic demographic information. Each participant then rated odor samples presented in clear glass 500 ml conical flasks with aluminum foil coverings. Participants were asked to rate the perceived masculinity or femininity of each odor on a 7-point scale (1 = below average, 4 = average, 7 = above average). Female samples were rated for femininity and male samples for masculinity. In order to avoid sensory overload, each rater judged samples from 5 donors (all male or all female), rating both the unfragranced and fragranced samples from these 5 donors (10 samples in total). In this way, the 20 male and 20 female donor samples were each divided into four groups of 5. The four groups of male odor samples were judged by similar numbers of female raters ($n = 19, 18, 18, 20$ for groups 1–4, respectively) and male raters ($n = 10, 11, 13, 11$). This was also true of female raters ($n = 20, 18, 20, 18$) and male raters ($n = 9, 13, 10, 12$) assessing female odor samples. Mean values were computed for each donor separately from ratings given by same- or opposite-sex participants, for both face and odor.

The order in which participants rated the unfragranced and fragranced samples was counterbalanced. As participants rated a subset of 5 of the 20 donors' samples, and as the focus of our study was on the comparison between fragranced and unfragranced samples, it was not deemed necessary to counterbalance the order of individual donor ratings within each odor condition.

2.5. Face rating procedure

Two online photograph rating tasks were created, one for male donors and one for female donors. Images appeared individually and participants rated faces for masculinity/femininity (depending on sex of the stimuli). The order in which each image appeared was randomized between participants. Participants who completed the face ratings also provided basic demographic information (age, sex, sexual orientation).

3. Results

3.1. Effects of fragrance on odor ratings

In order to investigate the effect of fragrance on sample ratings, we ran a repeated-measures ANOVA with two within-subjects factors, each with two levels (fragrance condition: fragranced, unfragranced; rater sex: same, opposite). As the male and female donor samples were assessed on an analogous but different scale (i.e., masculinity, femininity) we ran the analysis for each donor's sex separately.

For ratings given to male donors, there was a significant main effect of rater sex, with female raters giving higher ratings of masculinity to odor samples ($M = 3.51$, $SD = .62$) than male raters ($M = 3.31$, $SD = .68$), $F(1,19) = 5.657$, $p = .028$, $d = .31$. However, there was

overall no significant difference between unfragranced and fragranced samples, $F(1,19) = .219, p = .645$. There was also a significant interaction between the sex of the rater, and the ratings given to the two fragrance conditions, $F(1,19) = 6.103, p = .023$ (Fig. 1). Post hoc paired sample t -tests revealed that there was no significant difference between the ratings given by females to fragranced and unfragranced samples, $t(19) = -.857, p = .402$, or between ratings given by males to fragranced and unfragranced samples, $t(19) = 1.321, p = .202$. However further analysis did reveal a significant difference between ratings given by males ($M = 3.13, SD = .81$) and females ($M = 3.59, SD = .69$) to fragranced samples, $t(19) = 3.782, p = .001, d = .61$, but not between the ratings of unfragranced samples by males and females, $t(19) = -.337, p = .740$ (Fig. 1a).

The same analysis was then completed for the ratings obtained for female donors' odor samples. Here there was no significant main effect of rater sex, $F(1,19) = 1.556, p = .227$, but there was a significant main effect of fragrance, with the fragranced samples being rated as more feminine ($M = 3.76, SD = .93$) than the unfragranced samples ($M = 3.06, SD = .64$), $F(1,19) = 17.450, p = .001, d = .88$ (Fig. 1b). Unlike with the male donors, there was no significant interaction between rater sex and ratings given to the two fragrance conditions, $F(1,19) = .029, p = .866$. In exploratory post hoc analyses, we found that there were significant differences between ratings of fragranced and unfragranced samples given by both male and female raters, with fragranced samples being rated as more feminine than unfragranced samples, $t(19) = -3.12, p = .006, d = .82$; $t(19) = -4.96, p < .001, d = .78$ (Fig. 1b).

3.2. Relationship between face and odor ratings

Next, we investigated whether perception of femininity/masculinity was concordant across modalities by running correlational analyses using the mean ratings given to the odors and facial photographs of the donors.

For female raters, there was a significant positive correlation between their ratings of unfragranced odors and face ratings of female donors, $r(20) = .525, p = .018$ (Fig. 2a), as well as the fragranced odors and face ratings of female donors, $r(20) = .500, p = .025$ (Fig. 2b). Furthermore, we found a significant positive correlation between ratings given by females to unfragranced odors and male donors

faces, $r(20) = .450, p = .046$ (Fig. 2c), but the correlation between ratings of fragranced odor and male donors faces was not significant, $r(20) = .005, p = .982$ (Fig. 2d).

For ratings given by male participants, there were no significant correlations between unfragranced odor ratings and face ratings, $r(20) = .337, p = .147$ (Fig. 3a), or fragranced odor ratings and face ratings given to female donors, $r(20) = .174, p = .463$ (Fig. 3b). Additionally there were no significant correlations found between ratings of unfragranced odors and face ratings, $r(20) = .080, p = .739$ (Fig. 3c), or ratings of fragranced odors and face ratings given to male donors samples, $r(20) = .070, p = .768$ (Fig. 3d).

In order to further understand the differential effect that fragrance appeared to be having on ratings of masculinity and femininity given by same- and opposite-sex raters, we used a median split to divide the male and female donors into two groups; those who had received relatively high face ratings of masculinity/femininity and those who had received relatively low ratings. We then ran a repeated measures ANOVA, including fragrance as a within-subjects factor (fragranced, unfragranced), and high/low masculinity/femininity face ratings (split by the median) as a between-subjects factor. This analysis was run separately for male and female donors' ratings, as well as for same and opposite sex raters.

There was no significant main effect of fragrance condition for women rating men, $F(1,18) = .883, p = .360$. However, there was a significant interaction between ratings given by women to the male fragranced and unfragranced samples and the high/low score for facial masculinity, $F(1,18) = 4.841, p = .041$ (Fig. 4a). Post-hoc independent samples t -tests revealed that there was a significant difference between mean ratings given to the unfragranced samples of individuals in the high ($M = 3.83, SD = .65$) and low ($M = 3.03, SD = .74$) face masculinity groups, $t(18) = -2.55, p = .020, d = 1.13$, but not between the fragranced samples, $t(18) = -.17, p = .870$ (Fig. 4a). Paired samples t -tests further indicated that while there was a significant difference between the ratings for fragranced ($M = 3.56, SD = .66$) and unfragranced ($M = 3.04, SD = .74$) samples given to men grouped with 'low' facial masculinity, $t(9) = 3.36, p = .008, d = .74$, the same difference was not significant for the men grouped as having 'high' facial masculinity, $t(9) = -.71, p = .494$ (Fig. 4a). This model was re-run using ratings given by males, and as before, there was no significant main effect of fragrance, $F(1,18) = 1.66, p = .214$, and there was no

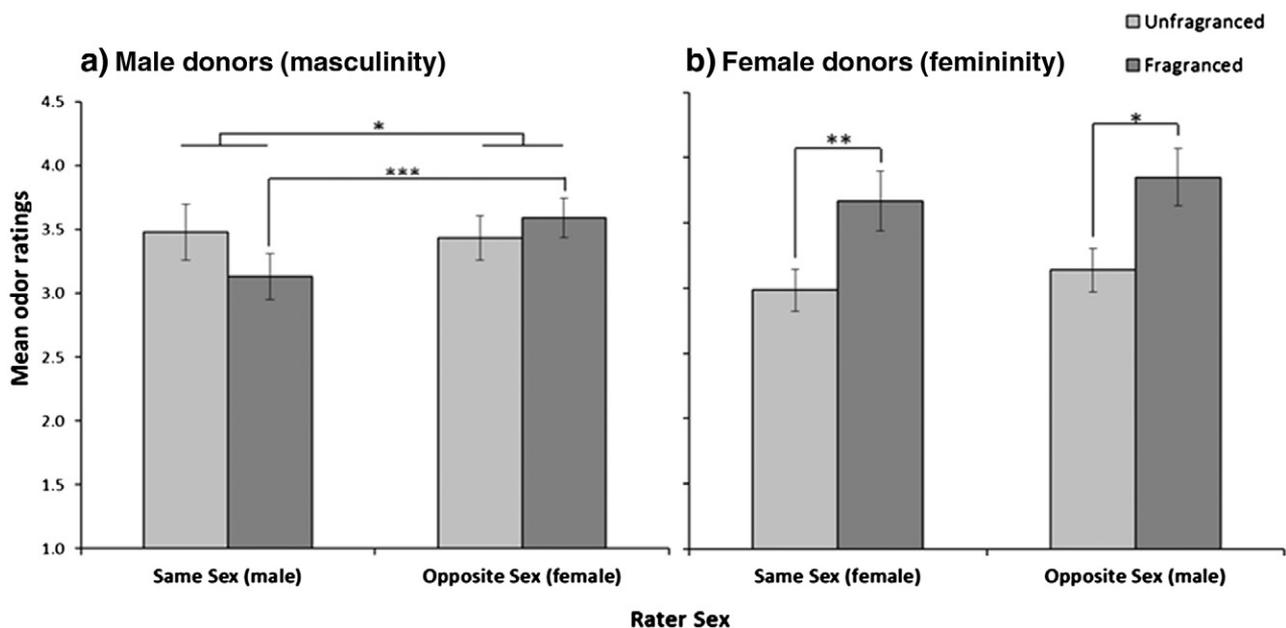

Fig. 1. a. Mean odor ratings given by male and female raters to male odor samples (masculinity). b. Mean odor ratings given by male and female raters to female odor samples (femininity). Bars represent mean \pm 1 SEM. Lines represent post hoc tests, ** $p < .01$, *** $p < .001$.

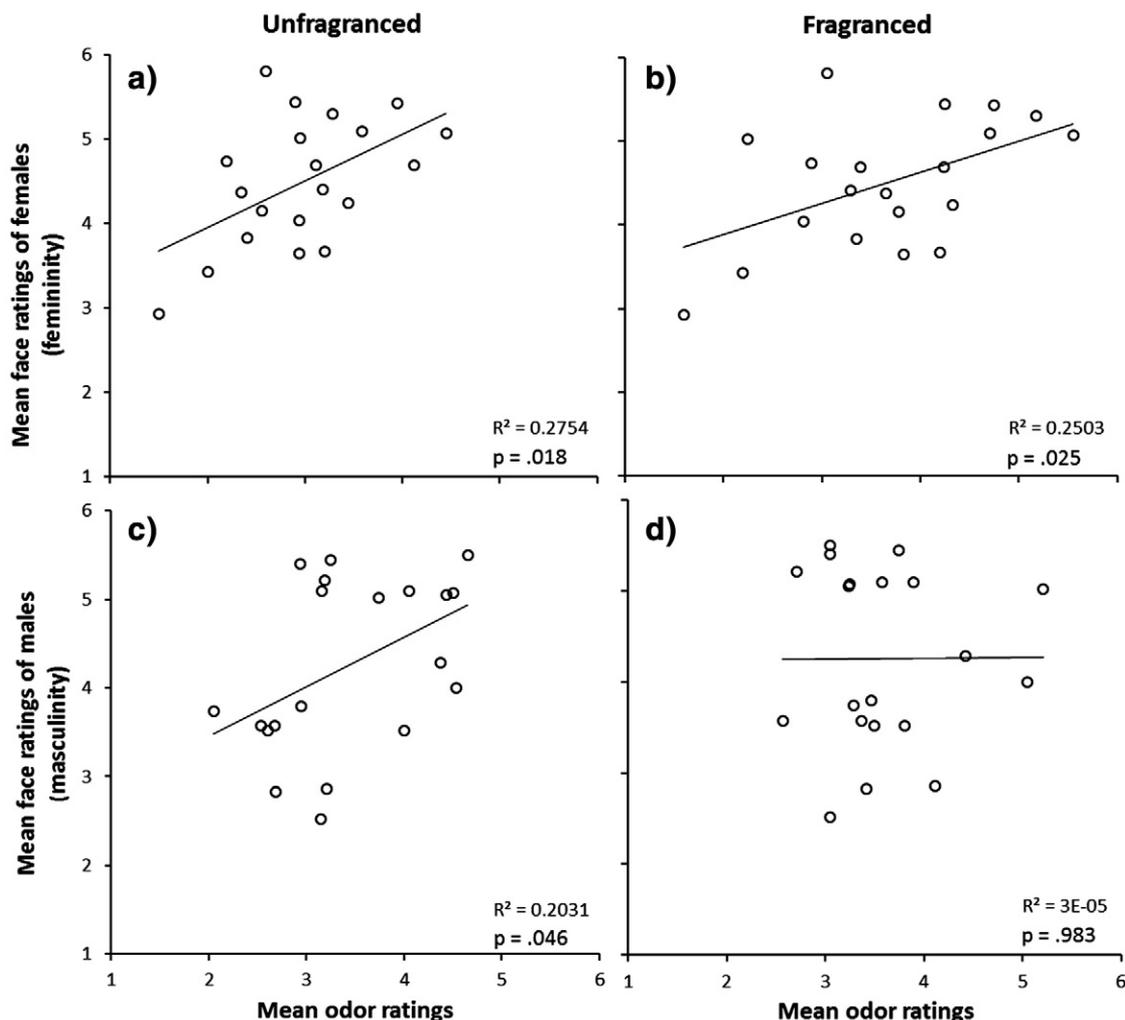

Fig. 2. Mean ratings of faces and odors (fragranced and unfragranced) given by female raters to both male and female donors. Male donors were rated for masculinity; female donors for femininity. Panels a and c show ratings of unfragranced odor samples and faces; panels b and d show ratings of fragranced odor samples and faces.

longer found to be a significant interaction between the ratings given to fragranced and unfragranced samples, and donors high/low face masculinity, $F(1,18) = .077$, $p = .785$ (Fig. 4c).

The same analysis was conducted for female donors' ratings. For ratings of femininity from males we found that, unlike with male donors ratings by females, there was a significant main effect of fragrance, $F(1,18) = 10.607$, $p = .004$, $d = .82$ with fragranced samples receiving higher ratings of femininity than unfragranced. However there was no significant analogous interaction between face ratings and odor ratings, $F(1,18) = 2.727$, $p = .116$, as had been found with the male donors (Fig. 4b). When analyzing responses from female raters there remained a main effect of fragrance, $F(1,18) = 23.328$, $p < .001$, with fragranced samples receiving on average higher ratings of femininity than unfragranced samples, and, as with male raters, there was no significant interaction between face and odor ratings, $F(1,18) = .042$, $p = .840$ (Fig. 4d).

4. Discussion

In this study we set out to investigate the effects of artificial fragrance use on the assessment of masculinity/femininity from body odor. In order to ascertain the impact of fragrance use, the relationships between face and odor ratings were investigated, both with and without fragrance.

Initially we were interested in how fragrances influence the perception of body odor, and the current analysis suggests that this effect differs depending on the sex of the odor donor and of the rater. When looking at male odors, female raters tended to give higher ratings of masculinity than male raters, especially in the fragranced samples, suggesting that women are perhaps more attentive to perceptual changes in these traits. Despite this, fragranced samples were not rated as being significantly more masculine than unfragranced samples by either men or women, and ratings of femininity for female samples did not differ between male and female raters. However, female samples were found to be significantly more feminine with the addition of a fragrance, when rated by men and women, supporting the idea that fragrance may be used, as other cosmetics appear to be (e.g. Russell, 2009), to enhance potentially biologically evolved preferences.

This pattern of results potentially reflects some difference between fragrances designed for males and females—female fragrances may be designed to be more feminine than male fragrances are masculine. This explanation is still consistent with a culture–gene coevolution framework. For example, there are negative associations with being perceived as extremely masculine, with one study finding that masculine faces had decreased perceptions of warmth, emotionality, honesty, cooperativeness and parental quality (Perrett et al., 1998). Females have also been found to prefer a moderate level of masculinity over an extreme level (Rhodes, Hickford, & Jeffery, 2000). We know of no

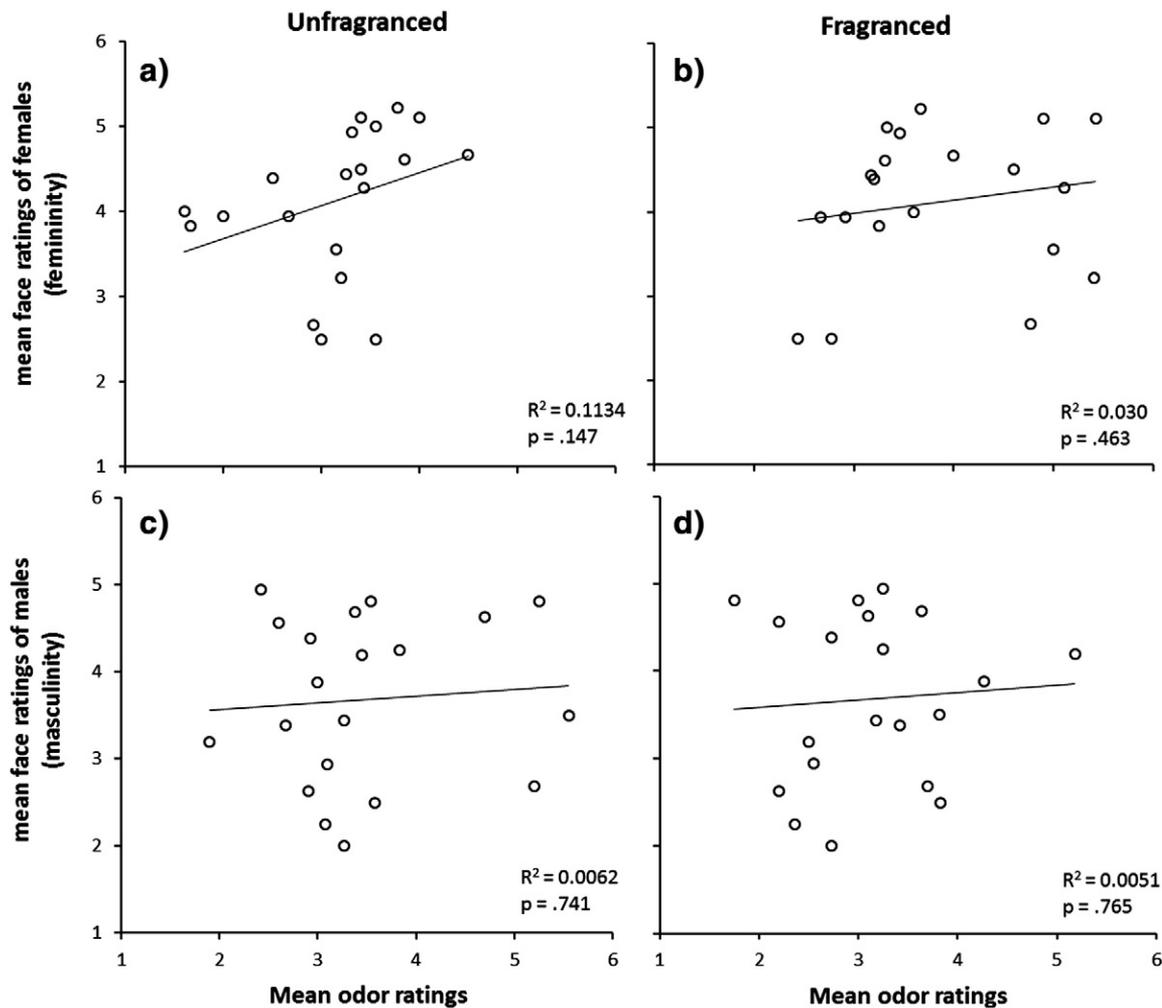

Fig. 3. Mean ratings of faces and odors (fragranced and unfragranced) given by male raters to both male and female donors. Male donors were rated for masculinity; female donors for femininity. Panels a and c show ratings of unfragranced odor samples and faces; panels b and d show ratings of fragranced odor samples and faces.

such studies that find analogous consequences of women being ‘too feminine’, with research suggesting that extreme feminization may not elicit these same negative responses (Rhodes et al., 2000), thus giving no reason to avoid over-feminizing a fragrance. Consequently, fragrance developers may avoid high levels of masculinity in male fragrances but not of femininity in female fragrances.

Our second prediction, that ratings of traits would be correlated across modalities, was partially supported, but this again appeared to be sex-dependent. There were significant correlations between ratings of masculinity and femininity given to unfragranced samples and faces which were rated by females (for both male and female samples), but this was not the case for ratings given by males (for both male and female samples). This finding builds on the one discussed above, further suggesting a sex-dependent attentiveness in perception of traits relating to masculinity/femininity. One potential explanation for this is that, due to sex differences in the physical/biological costs of reproduction (Trivers, 1972), it is more important for women to accurately assess these cues of potential mate quality, and so women show an increased sensitivity to the detection of this information. This is supported by previous work indicating that women are more sensitive in general than men are to odors (Brand & Millot, 2001), and that women place more importance on odor than males do in mate choice situations (Havlicek et al., 2008; Herz & Cahill, 1997). This sex difference may be exacerbated at certain times of a woman’s menstrual cycle, as women’s olfactory ability has been found to be heightened during the ovulatory phase of the cycle when estrogen levels and conception risk are high relative to

other points in the cycle (Doty, 1981; Navarrete-Palacios, Hudson, Reyes-Guerrero, & Guevara-Guzmán, 2003; for a recent meta-analysis see Nováková, Havlíček & Roberts, 2014). It could also be argued that women use more fragranced products than men do (Roberts et al., 2010) and that this additional experience may lead to an increased sensitivity/awareness. This is supported by recent findings that adults who reported higher engagement in odor-related activities during childhood show increased odor awareness and odor identification (Nováková, Valentova & Havlíček, 2014). Though this argument could likewise be reversed; women are more sensitive to odors, which leads them to use more fragranced products. While women may use more fragranced products, it is likely that the average man is exposed to a large number of fragranced products through daily interactions with women and their environment. In order to investigate this further future studies may benefit from measuring hygiene habits and individual differences in fragranced product use and exposure in raters.

The final hypothesis, that the addition of an artificial fragrance would prevent the accurate assessment of an individuals’ masculinity/femininity through body odor, again partially supported by the current findings, also appeared to be dependent upon the sex of the rater. A significant correlation between facial masculinity ratings and odor masculinity ratings by women for unfragranced samples was no longer statistically significant when fragranced samples were assessed. Further analysis using a median split on men’s facial masculinity also supported this: men with highly rated facial masculinity had significantly higher masculinity ratings of their unfragranced samples than those men

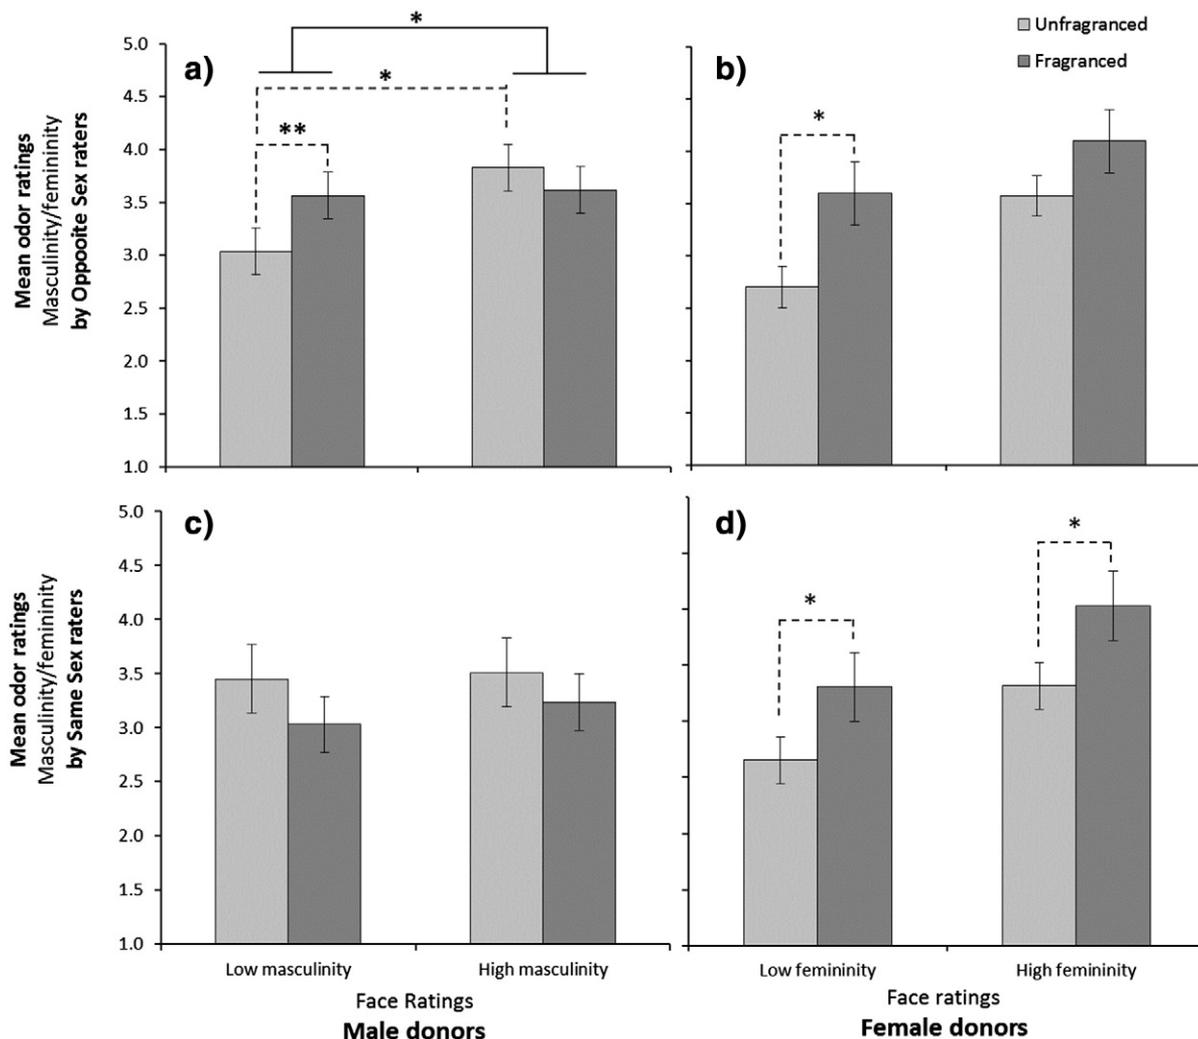

Fig. 4. Mean ratings of masculinity/femininity given by same and opposite sex raters for male and female donor samples, split by high/low face masculinity/femininity ratings. Bars represent mean \pm 1 SEM. Solid line represents significant interaction. Dashed lines represent post-hoc tests, * $p < .05$, ** $p < .01$. b and d depict main effects of fragrance which were not present in a and c.

with low face ratings. Importantly, this discrepancy between odor ratings in men with high and low facial masculinity disappeared with the addition of a fragrance. From an individual strategy perspective, and in support of the use of cultural practices to improve upon traits for which we show evolved preferences, this finding may suggest that those who already have desirable levels of masculinity achieve little benefit from wearing a fragrance. However, individuals low in these traits can potentially improve how others' perceive them through the application of a fragrance.

The story is less clear concerning the relationship between females' odors and face ratings. Unlike male raters, the significant correlation between ratings of femininity of odors and faces by female raters, when assessing the unfragranced samples, also remained in the fragranced samples. Further analysis indicated that women rating female odors did not discriminate between donors who had received high or low scores for facial femininity. This pattern was also noted in male ratings of female odors, in keeping with the lack of concordance between face and odor ratings given by men as discussed above. This finding provides further evidence of a sex-specific attentiveness in assessing these olfactory cues, with heterosexual women appearing to have more acute perception of these traits than males. This increased olfactory attentiveness may be useful in a mate choice context, both for inter- and intrasexual selection, aiding the choice of a mate but also perhaps allowing accurate assessment of potential female competitors. However, it must be noted

that fragrance use only appeared to *interfere* with accurate rating of male odors. Consequently, future research should investigate whether factors including current relationship status and relationship intent also play a role in an individuals' sensitivity/perception of these cues. Indeed, previous research has shown these factors are important contributors to mate preference. For instance, female preference for dominance in male body odor varies with relationship status (Havlicek, Roberts, & Flegr, 2005).

The current study provides evidence which further supports the cross-modality of mate quality cues in humans and their availability for use in a mate choice context, though it appears, at least with masculinity/femininity, to be specific to female perceivers. Additionally, as predicted using a culture–gene coevolution model, the findings suggest that current widespread fragrance use might potentially interfere with evolved body odor-based preferences, with fragrances potentially being used in an analogous fashion to other cosmetic products such as makeup (Havlicek & Roberts, 2013). At least for men, fragrance use appears to be enhancing levels of body odor masculinity, and this in turn appears to make it harder for females to discriminate between individual males based on this trait.

One notable limitation in the generalizability of this study is that, while a large sample of participant raters were recruited (239 odor raters and 130 image raters), the sample did have quite a narrow age range of both donors and participants. Future research may benefit

from establishing whether the findings are robust across a larger range of ages. Additionally, it is unclear how our findings can be extended to regularly cycling women, as all female donors were using hormonal contraceptives. This afforded us good control of the samples; however it prevents us from generalizing our findings across all reproductive age women. There was also potentially some noise introduced into the data since our female raters included women both on and off hormonal contraception and analysis did not account for cycle stage. Furthermore, participants used fragranced deodorants rather than simple fragrances, so there may be a confounding factor of body odor suppression coupled with fragrance addition. Future research should address these issues and carefully control the commercial products used. Finally, it is difficult to predict from the current study whether use of fragrance would interfere with the assessment of other mate choice relevant traits (e.g., health, personality, cycle stage), which may be influenced differently by the addition of artificial fragrances. Recent research indicates that fragrance use might have significant impact on body odor-based personality judgments (Sorokowska, Sorokowski, & Havlíček, 2016) and individual discrimination of body odors (Allen, Havlíček, & Roberts, 2015). Future research will be important to determine the wider impact of fragrance use on these and other important social variables.
